

It is not only arrivals. Departures cross us too.

Brockenhurst sits on the extended centreline of runway 08/26, so it is overflown **both ways**: by arrivals landing in from the east when the airport works westerly (about 77% of the time), and by departures climbing out east on the other 23%. We measured both from our own track data for the busiest month.

Brockenhurst is overflown both ways: low arrivals and full-power departures

Arrivals: measured heights of Bournemouth arrivals within 3 km of the village (minimums). Departures: runway-08 climb-outs within 3 km. The few very low departures are light aircraft or circuits, not airliners.

Height over Brockenhurst, July 2025. Arrivals come in low, mostly below the quiet-descent line. Runway-08 departures pass higher, but on full climb power.

23%

of departures use runway 08 (easterly ops), climbing out towards the village

71

runway-08 departures crossed the village in July, about 2.3 a day on easterly days

~6,900 ft

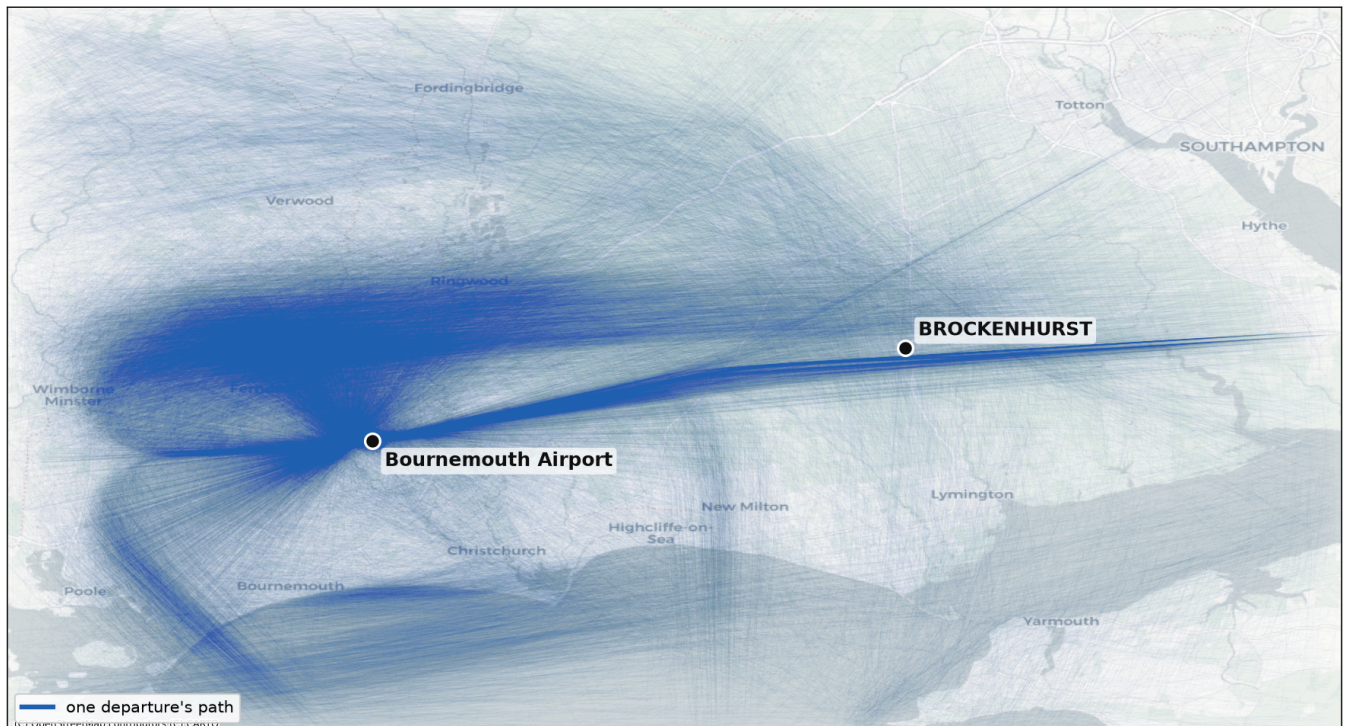

median departure height, higher than arrivals, but under full climb thrust

FACT The AIP already routes runway-08 departures on a **075° track, straight at Brockenhurst**, out to 5.6 DME before they turn. Today they turn before reaching the village (5.6 versus 9.7 miles), which spreads the noise out. Their height is less of an issue than arrivals, but the full-power climb makes each one loud.

The line a fixed route would lock in.

Every Bournemouth departure across three years, drawn from the aircraft's own GPS. The westerly departures fan away to the north-west, but the runway-08 climb-outs form a **distinct corridor running straight from the airport over Brockenhurst**. Today they spread out as they turn; the concern is what a precise satellite route would do to that corridor.

**Every Bournemouth departure fans out over Brockenhurst on easterly ops
2023 to 2025 (22,320 departures) - their own GPS tracks**

Every Bournemouth departure, 2023 to 2025 (22,320 flights), from their own GPS tracks. The easterly corridor over Brockenhurst is the runway-08 climb-out.

The risk under the new design. Satellite (PBN) routes are hyper-precise. A fixed departure route locked on that 075° line would remove today's dispersion and concentrate a full-power departure stream directly over the village, on top of the arrivals. As the airspace is redrawn through UKADS, our ask is simple: **no concentrated PBN departure route over Brockenhurst on easterly ops.**

Method: runway-08 departures identified from their easterly climb track, and counted where they pass within 3 km of the village. Heights are measured minimums. The handful of very low departures are light aircraft or circuit traffic, not airliners.
